Using Atomic Layer Deposition to Tune Surface Electronics and Catalytic Overpotentials of a Heterogeneous Electrocatalyst, Applied to IrO₂ as a Chlorine Evolution Reaction Catalyst for Wastewater Treatment in the Developing World

Rational optimization is a critical problem in the field of heterogeneous electrocatalysis, and more tools are needed to be able to rationally create and tune catalytic active sites. By coating the chlorine evolution reaction (CER) catalyst IrO₂ with a small number of TiO₂ atomic layer deposition (ALD) cycles, the catalytic parameters may be tuned in a Sabatier-like manner.

Potential of Zero Charge measurements show that adding different numbers of ALD cycles of TiO₂ tunes the surface electronics to an intermediate state between TiO₂ and IrO₂. This is a proof of concept that ALD can be used to tune the surface electronics of a catalyst for the environmentally important CER. Based on this, it may be possible to use ALD to tune the electronic properties of other electrocatalysts for reactions or to tune non-precious metal based catalysts to be active for critical reactions.

Fate of Organic Chemicals during Electrochemical Wastewater Treatment: Pharmaceuticals and Disinfection By-Products

Electrochemical processes holds promise for decentralized wastewater treatment, especially in developing countries where the infrastructure for conventional wastewater treatment is not available. While electrochemical treatment efficiently disinfects wastewater and removes nutrients, its ability to transform wastewater-derived trace organic contaminants, such as pharmaceuticals, is poorly understood. My talk will show that pharmaceuticals are efficiently transformed during electrochemical treatment, primarily via reaction with reactive chlorine species generated on mixed-metal anodes. Halogenated transformation products, which may be more toxic than parent compounds, also typically undergo further transformation during treatment. However, the production of regulated disinfection by-products, including haloacetic acids and trihalomethanes, during electrochemical wastewater treatment remains a cause for concern.

3:00 to 4:00 pm | Wednesday, 10/19/16
Guggenheim 101, Lees-Kubota Lecture Hall
Caltech Campus | resnick.caltech.edu

Caltech

THIS EVENT IS FREE AND OPEN TO THE PUBLIC. NO RSVP REQUIRED.
